Delving into the Realm of Complex Numbers: Problems and Solutions

Complex numbers, often described as "imaginary" numbers, are a fundamental concept in mathematics with applications across various fields, including engineering, physics, and signal processing. Understanding complex numbers is crucial for solving a wide range of problems and unlocking a deeper understanding of mathematical principles. This will explore common types of problems involving complex numbers, providing detailed explanations and solutions, ensuring a comprehensive understanding of this fascinating branch of mathematics.

The Foundations of Complex Numbers

Before diving into complex number problems, let's solidify our understanding of their fundamental characteristics.

- **The Imaginary Unit (i):** The foundation of complex numbers lies in the imaginary unit, denoted by 'i'. This unit is defined as the square root of -1 ($i^2 = -1$). Since the square of any real number is always positive, the square root of -1 is not a real number, hence the term "imaginary."
- **Complex Number Form:** A complex number is generally represented as 'z' and expressed as $z = a + bi$, where 'a' and 'b' are real numbers, and 'i' is the imaginary unit.
- 'a' is the real part of the complex number, denoted as $\text{Re}(z)$.
- 'b' is the imaginary part of the complex number, denoted as $\text{Im}(z)$.
- **Visualizing Complex Numbers:** Complex numbers can be visualized on the complex plane, a two-dimensional plane where the horizontal axis represents the real part (Re) and the vertical axis represents the imaginary part (Im). Each complex number can be plotted as a point on this plane, with its position determined by its real and imaginary components.

Basic Operations with Complex Numbers

Understanding basic arithmetic operations with complex numbers is crucial for solving various problems.

- **Addition and Subtraction:** Adding or subtracting complex numbers involves adding or subtracting their corresponding real and imaginary parts.
- **Example:** $(2 + 3i) + (1 - i) = (2+1) + (3-1)i = 3 + 2i$
- **Multiplication:** Multiplying complex numbers follows the distributive law, treating 'i' as a variable. Remember to simplify by substituting i^2 with -1.
- **Example:** $(2 + 3i) * (1 - i) = 2 - 2i + 3i - 3i^2 = 2 + i + 3 = 5 + i$
- **Division:** Dividing complex numbers involves multiplying both the numerator and denominator by the complex conjugate of the denominator. The complex conjugate of a complex number 'a + bi' is 'a - bi'.
- **Example:** $(2 + 3i) / (1 - i) = [(2 + 3i) * (1 + i)] / [(1 - i) * (1 + i)] = (2 + 2i + 3i + 3i^2) / (1^2 - i^2) = (-1 + 5i) / 2 = -1/2 + 5/2i$

Types of Complex Number Problems

Understanding the various types of complex number problems will allow you to identify the most appropriate approach for each scenario.

1. **Solving Equations:**
 - **Linear Equations:** These involve finding the value of a complex variable that satisfies a given linear equation.
 - **Example:** $2z + 3i = 5 - i$. To solve for z, isolate z on one side: $2z = 5 - 4i$, therefore $z = (5/2) - 2i$.
 - **Quadratic Equations:** Finding the roots of a quadratic equation involving complex coefficients.
 - **Example:** $z^2 + (2+i)z + 3i = 0$. This can be solved using the quadratic formula, substituting the values of the coefficients.
2. **Geometric Problems:**
 - **Finding the Distance**

between Two Complex Numbers: This involves applying the distance formula using the real and imaginary components of the complex numbers. • **Example**: Given $z_1 = 2 + 3i$ and $z_2 = 1 - i$, find the distance between them. The distance formula: $|z_1 - z_2| = \sqrt{[(2-1)^2 + (3+1)^2]} = \sqrt{(1 + 16)} = \sqrt{17}$. • **Determining the Angle between Complex Numbers**: Finding the angle between two complex numbers involves using the arctangent function and the components of the complex numbers. • **Example**: Find the angle between $z_1 = 2 + 3i$ and $z_2 = 1 - i$. The angle θ can be calculated using the formula: $\theta = \arctan(\text{Im}(z_2)/\text{Re}(z_2)) - \arctan(\text{Im}(z_1)/\text{Re}(z_1))$. **3. Modulus and Argument**: • Finding the Modulus of a Complex Number: The modulus of a complex number $z = a + bi$, denoted by $|z|$, represents the distance of the point representing 'z' from the origin in the complex plane. It is calculated using the formula: $|z| = \sqrt{a^2 + b^2}$. • **Example**: Find the modulus of $z = 3 - 4i$. $|z| = \sqrt{(3^2 + (-4)^2)} = \sqrt{25} = 5$. • **Finding the Argument of a Complex Number**: The argument of a complex number $z = a + bi$, denoted by $\arg(z)$, represents the angle between the positive real axis and the line joining the origin to the point representing 'z' in the complex plane. It is calculated using the formula: $\arg(z) = \arctan(b/a)$, considering the quadrant of 'z'. • **Example**: Find the argument of $z = -3 - 4i$. Here, 'z' lies in the third quadrant. Therefore, $\arg(z) = \arctan(-4/-3) + \pi = \pi + \arctan(4/3)$. **4. Polar Form of Complex Numbers**: • Converting from Rectangular to Polar Form: This involves expressing a complex number in terms of its modulus and argument. • **Example**: Convert $z = -3 + 4i$ to polar form. $|z| = \sqrt{((-3)^2 + 4^2)} = 5$ and $\arg(z) = \arctan(-4/-3) + \pi = \pi + \arctan(4/3)$. Therefore, the polar form of z is: $z = 5(\cos(\pi + \arctan(4/3)) + i \sin(\pi + \arctan(4/3)))$. • **Converting from Polar to Rectangular Form**: This involves expressing a complex number in terms of its real and imaginary components. • **Example**: Convert $z = 2(\cos(\pi/3) + i \sin(\pi/3))$ to rectangular form. Using the values of $\cos(\pi/3) = 1/2$ and $\sin(\pi/3) = \sqrt{3}/2$, we get $z = 2(1/2 + i(\sqrt{3}/2)) = 1 + i\sqrt{3}$. **5. De Moivre's Theorem**: • Calculating Powers of Complex Numbers: De Moivre's theorem provides a method for calculating powers of complex numbers expressed in polar form. It states that $(\cos\theta + i \sin\theta)^n = \cos(n\theta) + i \sin(n\theta)$. • **Example**: Calculate $(1 + i\sqrt{3})^8$. First, convert $(1 + i\sqrt{3})$ to polar form. $|1 + i\sqrt{3}| = 2$, $\arg(1 + i\sqrt{3}) = \pi/3$. Therefore, $(1 + i\sqrt{3}) = 2(\cos(\pi/3) + i \sin(\pi/3))$. Applying De Moivre's theorem: $[2(\cos(\pi/3) + i \sin(\pi/3))]^8 = 2^8(\cos(8\pi/3) + i \sin(8\pi/3)) = 256(\cos(2\pi/3) + i \sin(2\pi/3)) = 256(-1/2 + i(\sqrt{3}/2)) = -128 + 128i\sqrt{3}$. **6. Complex Conjugate and Properties**: • Finding the Complex Conjugate of a Complex Number: The complex conjugate of $z = a + bi$ is denoted as z^* and is obtained by changing the sign of the imaginary part: $z^* = a - bi$. • **Example**: The complex conjugate of $z = 2 + 3i$ is $z^* = 2 - 3i$. • Properties of Complex Conjugates: • Product of a complex number and its conjugate: $z * z^* = |z|^2$ • Sum of a complex number and its conjugate: $z + z^* = 2\text{Re}(z)$ • Difference of a complex number and its conjugate: $z - z^* = 2i\text{Im}(z)$

Unlocking the Mysteries: Complex Numbers Problems with Solutions

Ever stared at an equation that seems to defy the reality you know? Where the square root of a negative number pops up, leaving you scratching your head? Welcome to the fascinating world of complex numbers! While they might sound intimidating, these numbers are incredibly powerful tools in mathematics, physics, engineering, and beyond. This article is your friendly guide to understanding and solving common complex number problems, complete with clear, step-by-step solutions. So, buckle up, and let's dive into the world of $a + bi$!

What Exactly Are Complex Numbers?

Before we tackle problems, let's get a firm grasp on the fundamentals. A complex number is essentially a number that can be expressed in the form $a + bi$, where: a is the **real part** of the complex number. b is the **imaginary part** of the complex number. i is the **imaginary unit**, defined as the square root of -1 ($i^2 = -1$). Think of it as an extension of the real number system. Real numbers are just complex numbers where the imaginary part (b) is zero. For example, the real number 5 can be written as $5 + 0i$.

Why Do We Need Complex Numbers?

You might be wondering, "Why bother with imaginary stuff?" Well, complex numbers arise naturally when trying to solve certain algebraic equations. For instance, the equation $x^2 + 1 = 0$ has no real solutions. However, with complex numbers, we can rewrite it as $x^2 = -1$, leading to solutions $x = i$ and $x = -i$. Beyond pure mathematics, complex numbers are indispensable in fields like:

- **Electrical Engineering**: Analyzing AC circuits.
- **Quantum Mechanics**: Describing wave functions.
- **Signal Processing**: Filtering and analyzing signals.
- **Fluid Dynamics**: Modeling complex flows.

The ability to represent quantities with both magnitude and phase makes complex numbers incredibly versatile.

Basic Operations with Complex Numbers: The Building Blocks

Let's start with the fundamental operations. Solving problems involving complex numbers often boils down to mastering these basics.

Adding and Subtracting Complex Numbers

Adding and subtracting complex numbers is remarkably similar to adding and subtracting algebraic expressions with variables. You simply combine the real parts and the imaginary parts separately. Let $z_1 = a$

+ bi` and `z2 = c + di`. \*\*\*Addition:\*\* `z1 + z2 = (a + c) + (b + d)i` \*\*\*Subtraction:\*\* `z1 - z2 = (a - c) + (b - d)i`

Example Problem 1: Addition

Problem: Find the sum of `(3 + 4i)` and `(1 - 2i)`. **Solution:** Here, `z1 = 3 + 4i` and `z2 = 1 - 2i`. Real parts: `3 + 1 = 4` Imaginary parts: `4i + (-2i) = (4 - 2)i = 2i` So, `(3 + 4i) + (1 - 2i) = 4 + 2i`.

Example Problem 2: Subtraction

Problem: Subtract `(5 - i)` from `(2 + 3i)`. **Solution:** This means we need to compute `(2 + 3i) - (5 - i)`. Real parts: `2 - 5 = -3` Imaginary parts: `3i - (-i) = (3 - (-1))i = (3 + 1)i = 4i` So, `(2 + 3i) - (5 - i) = -3 + 4i`.

Multiplying Complex Numbers

Multiplying complex numbers uses the distributive property (similar to FOIL for binomials), remembering that `i^2 = -1`. Let `z1 = a + bi` and `z2 = c + di`. `z1 \* z2 = (a + bi)(c + di) = ac + adi + bci + bdi^2 = ac + adi + bci + bd(-1) = ac + adi + bci - bd = (ac - bd) + (ad + bc)i` (Grouping real and imaginary parts)

Example Problem 3: Multiplication

Problem: Calculate `(2 + 3i) \* (4 - i)`. **Solution:** Using the distributive property: `(2 + 3i) \* (4 - i) = 2(4) + 2(-i) + 3i(4) + 3i(-i) = 8 - 2i + 12i - 3i^2 = 8 + 10i - 3(-1) = 8 + 10i + 3 = (8 + 3) + 10i = 11 + 10i`

Dividing Complex Numbers

Division is perhaps the trickiest of the basic operations, but it becomes straightforward once you understand the concept of the **conjugate**. The conjugate of a complex number `a + bi` is `a - bi`. Multiplying a complex number by its conjugate always results in a real number: `(a + bi)(a - bi) = a^2 - (bi)^2 = a^2 - b^2i^2 = a^2 - b^2(-1) = a^2 + b^2`. To divide `z1 / z2`, we multiply both the numerator and the denominator by the conjugate of the denominator. Let `z1 = a + bi` and `z2 = c + di`. Then `z2`'s conjugate is `c - di`. `z1 / z2 = (a + bi) / (c + di) = [(a + bi) \* (c - di)] / [(c + di) \* (c - di)] = [(ac - adi + bci - bdi^2) / (c^2 - (di)^2)] = [(ac - adi + bci + bd) / (c^2 + d^2)] = [(ac + bd) + (bc - ad)i] / (c^2 + d^2) = (ac + bd)/(c^2 + d^2) + (bc - ad)/(c^2 + d^2)i`

Example Problem 4: Division

Problem: Evaluate `(1 + 2i) / (3 - 4i)`. **Solution:** The denominator is `3 - 4i`, so its conjugate is `3 + 4i`. Multiply the numerator and denominator by `3 + 4i`: `[(1 + 2i) \* (3 + 4i)] / [(3 - 4i) \* (3 + 4i)]` Numerator: `(1 + 2i)(3 + 4i) = 1(3) + 1(4i) + 2i(3) + 2i(4i) = 3 + 4i + 6i + 8i^2 = 3 + 10i + 8(-1) = 3 + 10i - 8 = -5 + 10i` Denominator: `(3 - 4i)(3 + 4i) = 3^2 - (4i)^2 = 9 - 16i^2 = 9 - 16(-1) = 9 + 16 = 25` So, `(1 + 2i) / (3 - 4i) = (-5 + 10i) / 25 = -5/25 + 10i/25 = -1/5 + 2/5 i`

Working with Powers and Roots of Complex Numbers

Moving beyond basic operations, we encounter problems involving powers and roots of complex numbers. This is where the **polar form** of complex numbers becomes incredibly useful.

The Polar Form of a Complex Number

A complex number `z = a + bi` can also be represented in polar form: `z = r(cos θ + i sin θ)`, often written as `z = r cis θ` or `z = r e^(iθ)` (Euler's form). * `r` is the **modulus** (or magnitude) of the complex number,

calculated as $r = |z| = \sqrt{a^2 + b^2}$. This is the distance from the origin to the point (a, b) in the complex plane. θ is the **argument** (or angle) of the complex number, calculated using $\tan \theta = b/a$, taking into account the quadrant of the complex number. This is the angle the line segment from the origin to (a, b) makes with the positive real axis.

De Moivre's Theorem: Powers Made Easy

De Moivre's Theorem provides a elegant way to calculate powers of complex numbers in polar form. If $z = r(\cos \theta + i \sin \theta)$, then for any integer n : $z^n = r^n (\cos(n\theta) + i \sin(n\theta))$

Example Problem 5: Powers

Problem: Calculate $(1 + i)^8$. **Solution:** First, convert $1 + i$ to polar form. Real part $a = 1$, Imaginary part $b = 1$. Modulus $r = \sqrt{1^2 + 1^2} = \sqrt{2}$. Argument θ : $\tan \theta = 1/1 = 1$. Since $(1, 1)$ is in the first quadrant, $\theta = \pi/4$ (or 45°). So, $1 + i = \sqrt{2} (\cos(\pi/4) + i \sin(\pi/4))$. Now, apply De Moivre's Theorem with $n = 8$: $(1 + i)^8 = (\sqrt{2})^8 (\cos(8 * \pi/4) + i \sin(8 * \pi/4)) = (2^{1/2})^8 (\cos(2\pi) + i \sin(2\pi)) = 2^4 (\cos(2\pi) + i \sin(2\pi)) = 16 (1 + i * 0) = 16$. This is a much simpler way than multiplying $(1 + i)$ by itself eight times!

Roots of Complex Numbers

Finding the n -th roots of a complex number is also simplified using its polar form. If $z = r(\cos \theta + i \sin \theta)$, then the n distinct n -th roots are given by: $z_k = r^{1/n} [\cos((\theta + 2\pi k)/n) + i \sin((\theta + 2\pi k)/n)]$ where $k = 0, 1, 2, \dots, n-1$.

Example Problem 6: Roots

Problem: Find the cube roots of $8i$. **Solution:** First, express $8i$ in polar form. $8i$ can be written as $0 + 8i$. Modulus $r = \sqrt{0^2 + 8^2} = 8$. Argument θ : $\tan \theta = 8/0$, which is undefined. Since $(0, 8)$ is on the positive imaginary axis, $\theta = \pi/2$ (or 90°). So, $8i = 8 (\cos(\pi/2) + i \sin(\pi/2))$. We need to find the cube roots, so $n = 3$. The formula for the roots is: $z_k = 8^{1/3} [\cos((\pi/2 + 2\pi k)/3) + i \sin((\pi/2 + 2\pi k)/3)]$. Now, let's find the roots for $k = 0, 1, 2$:
For $k = 0$: $z_0 = 2 [\cos((\pi/2)/3) + i \sin((\pi/2)/3)] = 2 [\cos(\pi/6) + i \sin(\pi/6)] = 2 [\sqrt{3}/2 + i * 1/2] = \sqrt{3} + i$
For $k = 1$: $z_1 = 2 [\cos((\pi/2 + 2\pi)/3) + i \sin((\pi/2 + 2\pi)/3)] = 2 [\cos(5\pi/6) + i \sin(5\pi/6)] = 2 [-\sqrt{3}/2 + i * 1/2] = -\sqrt{3} + i$
For $k = 2$: $z_2 = 2 [\cos((\pi/2 + 4\pi)/3) + i \sin((\pi/2 + 4\pi)/3)] = 2 [\cos(9\pi/6) + i \sin(9\pi/6)] = 2 [\cos(3\pi/2) + i \sin(3\pi/2)] = 2 [0 + i * (-1)] = -2i$
 So, the cube roots of $8i$ are $\sqrt{3} + i$, $-\sqrt{3} + i$, and $-2i$.

More Advanced Complex Number Problems

As you delve deeper, you'll encounter problems that combine these concepts or introduce new ones.

Solving Quadratic Equations with Complex Roots

As mentioned earlier, complex numbers are essential for solving quadratic equations where the discriminant is negative. The quadratic formula $x = [-b \pm \sqrt{b^2 - 4ac}] / 2a$ is your best friend here.

Example Problem 7: Quadratic Equation **Problem:** Solve the equation $x^2 - 4x + 5 = 0$.

Solution: Using the quadratic formula, where $a = 1$, $b = -4$, $c = 5$. The discriminant is $\Delta = b^2 - 4ac = (-4)^2 - 4(1)(5) = 16 - 20 = -4$. Since the discriminant is negative, we expect complex roots. $x = [-(-4) \pm \sqrt{-4}] / (2 * 1) = [4 \pm \sqrt{4 * -1}] / 2 = [4 \pm \sqrt{4} * \sqrt{-1}] / 2 = [4 \pm$

$2i] / 2$ Now, separate the two solutions: $x_1 = (4 + 2i) / 2 = 4/2 + 2i/2 = 2 + i$ $x_2 = (4 - 2i) / 2 = 4/2 - 2i/2 = 2 - i$ The solutions are $2 + i$ and $2 - i$.

Understanding the Complex Plane

The **complex plane** (also known as the Argand plane or Gauss plane) is a graphical representation of complex numbers. The horizontal axis represents the real part, and the vertical axis represents the imaginary part. This visual aid is crucial for understanding geometric interpretations of complex number operations. For example, multiplication by i corresponds to a 90° counter-clockwise rotation in the complex plane.

Euler's Identity and its Implications

A truly remarkable equation that bridges complex numbers with fundamental mathematical constants is Euler's Identity: $e^{i\pi} + 1 = 0$. This equation, derived from Euler's formula $e^{ix} = \cos x + i \sin x$, shows a profound connection between e , i , π , 1 , and 0 . While not a typical "problem to solve" in the same way as the others, understanding its derivation and implications is a significant step in mastering complex numbers.

Tips for Tackling Complex Number Problems

Common Complex Numbers Problems and Their Solutions

Working with complex numbers involves extending familiar arithmetic operations to a new domain. The fundamental building block is the imaginary unit 'i'. A complex number is generally expressed in the form $(a + bi)$, where 'a' is the real part and 'b' is the imaginary part. Let's explore some typical problem categories.

1. Arithmetic Operations with Complex Numbers

The foundational problems involve performing addition, subtraction, multiplication, and division on complex numbers. These operations are analogous to polynomial operations, with the crucial understanding that $i^2 = -1$.

Problem 1: Addition and Subtraction

Problem: Given two complex numbers, $(z_1 = 3 + 4i)$ and $(z_2 = 1 - 2i)$, find $(z_1 + z_2)$ and $(z_1 - z_2)$.

Solution: To add or subtract complex numbers, we combine the real parts and the imaginary parts separately.

Addition: $(z_1 + z_2 = (3 + 4i) + (1 - 2i))$ $(z_1 + z_2 = (3 + 1) + (4 - 2)i)$ $(z_1 + z_2 = 4 + 2i)$

Subtraction: $(z_1 - z_2 = (3 + 4i) - (1 - 2i))$ $(z_1 - z_2 = (3 - 1) + (4 - (-2))i)$ $(z_1 - z_2 = 2 + 6i)$

Problem 2: Multiplication

Problem: Calculate the product of $(z_1 = 2 + 3i)$ and $(z_2 = 4 - i)$.

Solution: We use the distributive property (similar to FOIL for binomials) and remember that $(i^2 = -1)$.

$$\begin{aligned} (z_1 \times z_2) &= (2 + 3i)(4 - i) \\ (z_1 \times z_2) &= 2(4) + 2(-i) + 3i(4) + 3i(-i) \\ (z_1 \times z_2) &= 8 - 2i + 12i - 3i^2 \\ (z_1 \times z_2) &= 8 + 10i - 3(-1) \quad (\text{since } i^2 = -1) \\ (z_1 \times z_2) &= 8 + 10i + 3 \\ (z_1 \times z_2) &= 11 + 10i \end{aligned}$$

Problem 3: Division

Problem: Find the quotient $\frac{z_1}{z_2}$, where $(z_1 = 1 + 2i)$ and $(z_2 = 3 - i)$.

Solution: Division of complex numbers is performed by multiplying both the numerator and the denominator by the conjugate of the denominator. The conjugate of a complex number $(a + bi)$ is $(a - bi)$. This process effectively removes the imaginary part from the denominator.

The conjugate of $(z_2 = 3 - i)$ is $(\bar{z}_2 = 3 + i)$.

$$\frac{z_1}{z_2} = \frac{1 + 2i}{3 - i} \quad \frac{z_1}{z_2} = \frac{(1 + 2i)(3 + i)}{(3 - i)(3 + i)}$$

Numerator: $((1 + 2i)(3 + i) = 1(3) + 1(i) + 2i(3) + 2i(i))$ $(= 3 + i + 6i + 2i^2)$ $(= 3 + 7i + 2(-1))$ $(= 3 + 7i - 2)$ $(= 1 + 7i)$

Denominator: $((3 - i)(3 + i) = 3(3) + 3(i) - i(3) - i(i))$ $(= 9 + 3i - 3i - i^2)$ $(= 9 - (-1))$ $(= 9 + 1)$ $(= 10)$
(Note: The denominator is always a real number, equal to $(a^2 + b^2)$ for $(a + bi)$.)

So, $\frac{z_1}{z_2} = \frac{1 + 7i}{10} = \frac{1}{10} + \frac{7}{10}i$.

2. Solving Equations Involving Complex Numbers

Complex numbers are fundamental to solving polynomial equations, especially those that do not have real roots, as guaranteed by the Fundamental Theorem of Algebra.

Problem 4: Quadratic Equations

Problem: Solve the quadratic equation $(x^2 - 4x + 5 = 0)$.

Solution: We can use the quadratic formula: $(x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a})$. Here, $(a = 1)$, $(b = -4)$, and $(c = 5)$.

$$\begin{aligned} (x &= \frac{-(-4) \pm \sqrt{(-4)^2 - 4(1)(5)}}{2(1)}) \\ (x &= \frac{4 \pm \sqrt{16 - 20}}{2}) \\ (x &= \frac{4 \pm \sqrt{-4}}{2}) \end{aligned}$$

Since $(\sqrt{-4} = \sqrt{4 \times -1} = \sqrt{4} \times \sqrt{-1} = 2i)$, we have:

$$(x = \frac{4 \pm 2i}{2}) \quad (x = \frac{4}{2} \pm \frac{2i}{2}) \quad (x = 2 \pm i)$$

The solutions are $(x = 2 + i)$ and $(x = 2 - i)$. This demonstrates how complex numbers arise naturally when solving equations with negative discriminants.

Problem 5: Equations with Complex Coefficients

Problem: Find the value of (z) if $((2 + i)z = 5 - 3i)$.

Solution: This is a simple linear equation where we need to isolate (z) . We can do this by dividing both sides by $(2 + i)$.

$$(z = \frac{5 - 3i}{2 + i})$$

Now, we multiply the numerator and denominator by the conjugate of the denominator $(2 - i)$.

$$(z = \frac{(5 - 3i)(2 - i)}{(2 + i)(2 - i)})$$

Numerator: $((5 - 3i)(2 - i) = 5(2) + 5(-i) - 3i(2) - 3i(-i)) (= 10 - 5i - 6i + 3i^2) (= 10 - 11i + 3(-1)) (= 10 - 11i - 3) (= 7 - 11i)$

Denominator: $((2 + i)(2 - i) = 2^2 - (i)^2 = 4 - (-1) = 4 + 1 = 5)$

So, $(z = \frac{7 - 11i}{5} = \frac{7}{5} - \frac{11}{5}i)$.

3. Complex Numbers in Polar Form

While the rectangular form $(a + bi)$ is intuitive for arithmetic, the [polar form](#), $(r(\cos \theta + i \sin \theta))$ or $(re^{i\theta})$ (Euler's form), is invaluable for understanding multiplication, division, exponentiation, and roots of complex numbers, especially in trigonometric contexts. Here, 'r' is the magnitude (or modulus) and ' θ ' is the argument (or angle).

Problem 6: Converting Between Forms

Problem: Convert the complex number $(z = 1 - \sqrt{3}i)$ from rectangular form to polar form.

Solution: First, calculate the magnitude (r) : $(r = |z| = \sqrt{a^2 + b^2})$ For $(z = 1 - \sqrt{3}i)$, $(a = 1)$ and $(b = -\sqrt{3})$. $(r = \sqrt{1^2 + (-\sqrt{3})^2} = \sqrt{1 + 3} = \sqrt{4} = 2)$.

Next, calculate the argument (θ) . The argument (θ) is the angle such that $(\cos \theta = \frac{a}{r})$ and $(\sin \theta = \frac{b}{r})$. $(\cos \theta = \frac{1}{2})$ $(\sin \theta = \frac{-\sqrt{3}}{2})$

The angle (θ) that satisfies these conditions in the fourth quadrant (since 'a' is positive and 'b' is negative) is $(\theta = -\frac{\pi}{3})$ radians (or (300°)).

Therefore, the polar form is $(z = 2(\cos(-\frac{\pi}{3}) + i \sin(-\frac{\pi}{3})))$ or $(z = 2e^{-i\pi/3})$.

Problem 7: Multiplication in Polar Form

Problem: Given $(z_1 = 2(\cos(\frac{\pi}{6}) + i \sin(\frac{\pi}{6})))$ and $(z_2 = 3(\cos(\frac{\pi}{3}) + i \sin(\frac{\pi}{3})))$, find $(z_1 \times z_2)$.

Solution: To multiply complex numbers in polar form, we multiply their magnitudes and add their arguments.

$(r_1 r_2 = 2 \times 3 = 6)$ $(\theta_1 + \theta_2 = \frac{\pi}{6} + \frac{\pi}{3} = \frac{\pi}{2})$
 $(\frac{2\pi}{6} = \frac{\pi}{3})$

So, $(z_1 \times z_2 = 6(\cos(\frac{\pi}{2}) + i \sin(\frac{\pi}{2})))$. Since $(\cos(\frac{\pi}{2}) = 0)$ and $(\sin(\frac{\pi}{2}) = 1)$, this simplifies to $(6(0 + i(1)) = 6i)$.

Problem 8: De Moivre's Theorem (Exponentiation)

Problem: Calculate $((1 + i)^6)$.

Solution: First, convert $(1 + i)$ to polar form. Magnitude $(r = \sqrt{1^2 + 1^2} = \sqrt{2})$. Argument $(\theta = \arctan(\frac{1}{1}) = \frac{\pi}{4})$ (since it's in the first quadrant). So, $(1 + i = \sqrt{2}(\cos(\frac{\pi}{4}) + i \sin(\frac{\pi}{4})))$.

De Moivre's Theorem states that for a complex number $(z = r(\cos \theta + i \sin \theta))$, $(z^n = r^n(\cos(n\theta) + i \sin(n\theta)))$.

Here, $(n = 6)$. $((1 + i)^6 = (\sqrt{2})^6 (\cos(6 \times \frac{\pi}{4}) + i \sin(6 \times \frac{\pi}{4})))$
 $((\sqrt{2})^6 = (2^{1/2})^6 = 2^3 = 8)$. $(6 \times \frac{\pi}{4} = \frac{3\pi}{2})$.

So, $((1 + i)^6 = 8(\cos(\frac{3\pi}{2}) + i \sin(\frac{3\pi}{2})))$. Since $(\cos(\frac{3\pi}{2}) = 0)$ and $(\sin(\frac{3\pi}{2}) = -1)$, $((1 + i)^6 = 8(0 + i(-1)) = -8i)$.

4. Geometric Interpretation of Complex Numbers

Complex numbers can be visualized on the complex plane (also known as the Argand plane), where the horizontal axis represents the real part and the vertical axis represents the imaginary part. This geometric perspective is crucial for understanding operations like multiplication and for visualizing solutions to equations.

Problem 9: Geometric Representation of Operations

Problem: Consider the complex numbers $(z_1 = 1 + i)$ and $(z_2 = 2 - i)$. Represent (z_1) , (z_2) , $(z_1 + z_2)$, and $(z_1 - z_2)$ on the complex plane.

Solution: - $(z_1 = 1 + i)$ corresponds to the point (1, 1) on the complex plane. - $(z_2 = 2 - i)$ corresponds to the point (2, -1) on the complex plane. - $(z_1 + z_2 = (1 + i) + (2 - i) = 3)$. This corresponds to the point (3, 0). Geometrically, the sum of two complex numbers is the diagonal of the parallelogram formed by the vectors representing the two complex numbers from the origin. - $(z_1 - z_2 = (1 + i) - (2 - i) = -1 + 2i)$. This corresponds to the point (-1, 2). Geometrically, the difference $(z_1 - z_2)$ can be visualized as the vector from the point representing (z_2) to the point representing (z_1) .

(A visual representation would show these points and vectors on a graph.)

5. Roots of Complex Numbers (Roots of Unity)

Finding the n th roots of a complex number is a classic application of polar form and De Moivre's theorem. The (n) th roots of a complex number $(z = r(\cos \theta + i \sin \theta))$ are given by: $\sqrt[n]{r} \left(\cos \left(\frac{\theta + 2k\pi}{n} \right) + i \sin \left(\frac{\theta + 2k\pi}{n} \right) \right)$ for $(k = 0, 1, 2, \dots, n-1)$.

Problem 10: Cube Roots of a Complex Number

Problem: Find the three cube roots of $(z = 8)$.

Solution: First, represent $(z = 8)$ in polar form. $(r = |8| = 8)$. $(\theta = 0)$ (since 8 lies on the positive real axis). So, $(z = 8(\cos(0) + i \sin(0)))$.

We are looking for the cube roots $(n=3)$, so (k) will take values 0, 1, and 2.

For $(k = 0)$: $\sqrt[3]{8} \left(\cos \left(\frac{0 + 2(0)\pi}{3} \right) + i \sin \left(\frac{0 + 2(0)\pi}{3} \right) \right) = 2(\cos(0) + i \sin(0)) = 2(1 + 0i) = 2$

For $(k = 1)$: $\sqrt[3]{8} \left(\cos \left(\frac{0 + 2(1)\pi}{3} \right) + i \sin \left(\frac{0 + 2(1)\pi}{3} \right) \right) = 2 \left(\cos \left(\frac{2\pi}{3} \right) + i \sin \left(\frac{2\pi}{3} \right) \right) = 2 \left(-\frac{1}{2} + i \frac{\sqrt{3}}{2} \right) = -1 + i\sqrt{3}$

For $(k = 2)$: $\sqrt[3]{8} \left(\cos \left(\frac{0 + 2(2)\pi}{3} \right) + i \sin \left(\frac{0 + 2(2)\pi}{3} \right) \right) = 2 \left(\cos \left(\frac{4\pi}{3} \right) + i \sin \left(\frac{4\pi}{3} \right) \right) = 2 \left(-\frac{1}{2} - i \frac{\sqrt{3}}{2} \right) = -1 - i\sqrt{3}$

The three cube roots of 8 are (2) , $(-1 + i\sqrt{3})$, and $(-1 - i\sqrt{3})$. Geometrically, these roots are equally spaced around a circle of radius 2 in the complex plane.

Questions & Answers About complex numbers problems with solutions

No	Question	Answer
1	What's the easiest way to multiply two complex numbers, like $(2 + 3i)$ and $(1 - 4i)$?	Use the FOIL method (First, Outer, Inner, Last), just like with binomials. $(2 + 3i)(1 - 4i) = (2*1) + (2*-4i) + (3i*1) + (3i*-4i) = 2 - 8i + 3i - 12i^2$. Since $i^2 = -1$, this becomes $2 - 5i - 12(-1) = 2 - 5i + 12 = 14 - 5i$.
2	How do I find the modulus (or absolute value) of a complex number like $z = -5 + 12i$?	The modulus of a complex number $z = a + bi$ is found using the Pythagorean theorem: $ z = \sqrt{a^2 + b^2}$. For $z = -5 + 12i$, $ z = \sqrt{(-5)^2 + 12^2} = \sqrt{25 + 144} = \sqrt{169} = 13$.
3	What does it mean to find the conjugate of a complex number, and how do I do it for $z = 7 - 2i$?	The conjugate of a complex number $z = a + bi$ is found by simply changing the sign of the imaginary part. The conjugate of $z = 7 - 2i$ is denoted as $\bar{z}$ and is $7 + 2i$. It's useful for simplifying divisions and finding roots.
4	I'm struggling to divide complex numbers. How do I divide $(3 + 2i)$ by $(1 - i)$?	To divide complex numbers, multiply both the numerator and the denominator by the conjugate of the denominator. The conjugate of $(1 - i)$ is $(1 + i)$. So, $[(3 + 2i) / (1 - i)] * [(1 + i) / (1 + i)] = (3 + 3i + 2i + 2i^2) / (1^2 - i^2) = (3 + 5i - 2) / (1 - (-1)) = (1 + 5i) / 2 = 1/2 + 5/2 i$.
5	What's the significance of the imaginary unit 'i' in complex numbers?	The imaginary unit 'i' is defined as the square root of -1 ($i = \sqrt{-1}$). It allows us to solve equations that have no real solutions, such as $x^2 + 1 = 0$, where $x = \pm i$. It extends the number system and is fundamental to many areas of science and engineering.
6	How can I represent a complex number like $z = 1 + \sqrt{3}i$ graphically on the complex plane?	On the complex plane, the horizontal axis represents the real part and the vertical axis represents the imaginary part. For $z = 1 + \sqrt{3}i$, you would plot a point at $(1, \sqrt{3})$. The distance from the origin to this point is the modulus, and the angle it makes with the positive real axis is the argument.
7	What are De Moivre's theorem and its applications for powers of complex numbers?	De Moivre's theorem states that for any complex number in polar form $r(\cos \theta + i \sin \theta)$ and any integer n , $[r(\cos \theta + i \sin \theta)]^n = r^n(\cos(n\theta) + i \sin(n\theta))$. This provides a straightforward way to calculate powers and roots of complex numbers, which is much more complex using algebraic forms.
