

Definition of product in math terms

** Unlock the precise mathematical definition of "product." Learn about different types of products – from simple multiplication to Cartesian and scalar products – with clear examples and applications. Master this fundamental concept for improved math comprehension. Understand its significance in various fields from basic arithmetic to advanced linear algebra. The term "product" in mathematics refers to the result of a multiplication operation. While seemingly simple at its core (e.g., $2 \times 3 = 6$, where 6 is the product), the mathematical definition of "product" extends far beyond basic arithmetic to encompass diverse contexts and more complex mathematical structures. This subtle shift in meaning allows us to apply the concept of "product" to sophisticated mathematical systems, enriching our understanding of these systems. Let's delve deeper into the various contexts where the term "product" finds meaning:

1. The Product in Elementary Arithmetic: **In its most fundamental sense, the product is the result obtained by multiplying two or more numbers. These numbers are called factors. For instance:**

- $5 \times 7 = 35$ (Here, 5 and 7 are factors, and 35 is their product.)
- $2 \times 4 \times 6 = 48$ (The product of 2, 4, and 6 is 48.)

This basic understanding forms the cornerstone of many advanced mathematical concepts related to products. The "product" in this context is straightforward and intuitively understood.

2. The Cartesian Product (Set Theory): **Moving beyond simple arithmetic, the concept of a product takes on a different meaning in set theory. The Cartesian product represents all possible ordered pairs (or tuples) formed by combining elements from two or more sets. For example, let's consider two sets:**

- Set A = {1, 2}
- Set B = {a, b}

The Cartesian product of A and B is denoted by $A \times B$ and is calculated as:

$$A \times B = \{(1, a), (1, b), (2, a), (2, b)\}$$

| Set A | Set B | $A \times B$ (Ordered Pairs) |

1	a	(1, a)
1	b	(1, b)
2	a	(2, a)
2	b	(2, b)

The Cartesian product extends to more than two sets, resulting in ordered triples, quadruples, and so on. This concept is crucial in various areas, including relational databases, where it helps to model relationships between entities.

3. The Dot Product (Scalar Product) (Linear Algebra): *In linear algebra, we encounter the dot product (also known as the scalar product), a crucial operation on vectors. The dot product of two vectors results in a scalar (a single number). This calculation involves multiplying corresponding entries of the vectors and summing the results. Let's illustrate with two vectors:*

- Vector $u = (1, 2, 3)$
- Vector $v = (4, 5, 6)$

The dot product $u \cdot v$ is calculated as:

$$u \cdot v = (1 \times 4) + (2 \times 5) + (3 \times 6) = 4 + 10 + 18 = 32$$

The dot product has numerous applications, including calculating work done by a force, determining the angle between two vectors, and projecting one vector onto another.

4. The Cross Product (Vector Product) (Linear Algebra): **Another significant type of product in linear algebra is the cross product (also known as the vector product), applicable only to vectors in three-dimensional space. Unlike the dot product, the cross product results in another vector, orthogonal (perpendicular) to both original vectors. Calculating the cross product involves a more complex formula using determinants: For two vectors $u = (u_1, u_2, u_3)$ and $v = (v_1, v_2, v_3)$, the cross product $u \times v$ is often represented using a 3x3 determinant:**

$$u \times v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ u_1 & u_2 & u_3 \\ v_1 & v_2 & v_3 \end{vmatrix}$$

This determinant calculation yields a vector with components:

$$(u_2v_3 - u_3v_2)\mathbf{i} - (u_1v_3 - u_3v_1)\mathbf{j} + (u_1v_2 - u_2v_1)\mathbf{k}$$

The cross product is pivotal for determining areas of parallelograms formed by vectors, calculating torques, and other applications in physics and engineering.

5. Product of Matrices (Linear Algebra): **Matrix multiplication, often simply referred to as the matrix product, is a fundamental operation in linear algebra. Unlike scalar multiplication, matrix multiplication is not element-wise. The result is a new matrix where each element is determined by the dot product of a row from the first matrix and a column from the second matrix. The dimensions of the matrices must satisfy specific conditions for this operation to be valid.**

For example, if A is an MxN matrix and B is an NxP matrix, their product AB will be an MxP matrix. The detailed calculation involves the dot product of each row of 'A' with each column of 'B'. Advantages of Understanding the Mathematical Definition of Product: • Enhanced Mathematical Skills: **A strong grasp of product concepts opens doors to more advanced mathematical topics and applications.** • Improved Problem-Solving: **Understanding various types of products assists in solving complex problems across diverse fields.** • Interdisciplinary Applications: The product concept transcends pure mathematics; it plays a significant role in physics, engineering, computer science, and numerous others.

What Exactly is a "Product" in Math?

Ever found yourself staring at a math problem and wondering, "What does 'product' even mean here?" You're not alone! While it might seem straightforward, the term "product" in mathematics carries a specific meaning that's fundamental to so many areas of study. It's not just about multiplying numbers;

it's a concept that extends from basic arithmetic to complex algebra and beyond. Let's dive in and unpack the definition of a product in math terms, making sure to sprinkle in some related keywords and LSI (Latent Semantic Indexing) terms along the way.

The Core Definition: Multiplication's Grand Result

At its heart, the **product in mathematics** is the result obtained when you perform the operation of **multiplication**. Think of it as the answer you get after multiplying two or more numbers or quantities together. It's the final output of a multiplication expression.

Simple Examples to Get Us Started

Let's start with the basics. If you see an expression like:

$$3 \times 5 = 15$$

Here, the numbers 3 and 5 are called the **factors**. The result, 15, is the **product**. It's the numerical outcome of multiplying those two factors.

Similarly:

$$7 \times 4 = 28$$

In this case, 7 and 4 are the factors, and 28 is their product.

The beauty of multiplication is that it's commutative, meaning the order of the factors doesn't change the product: 3×5 is the same as 5×3 , both equaling 15.

Beyond Two Numbers: Multiple Factors and the Product

The concept of a product isn't limited to just two numbers. You can multiply three, four, or even more numbers together to find their collective product.

Consider this:

$$2 \times 3 \times 4 = ?$$

You can solve this step-by-step: first, $2 \times 3 = 6$. Then, multiply that result by the next factor: $6 \times 4 = 24$. So, the product of 2, 3, and 4 is 24.

This is where the idea of a **product of multiple numbers** comes into play. It's the single value that represents the cumulative effect of multiplying all those numbers.

The Product in Algebraic Expressions

As we move into algebra, the definition of a product expands. Instead of just numbers, we often deal with variables and expressions. The fundamental principle, however, remains the same: a product is the result of multiplication.

Multiplying Variables

If you have variables like 'x' and 'y', their product is simply written as xy . This implies x multiplied by y.

Example:

$a * b * c$ is the product of the variables a , b , and c .

Expressions Involving Variables and Numbers

When we combine numbers and variables, the product still signifies multiplication.

Consider the expression: $5y$.

This means 5 multiplied by y . Here, 5 is a numerical coefficient, and ' y ' is the variable. Their product is $5y$.

Another example: $2ab$. This represents 2 multiplied by a multiplied by b . The factors are 2, a , and b , and their product is $2ab$.

Products of Algebraic Expressions

Things get a bit more interesting when we multiply algebraic expressions. Here, we often use distribution to find the product.

Let's look at multiplying a binomial by a monomial:

$$3x(x + 2)$$

To find the product, we distribute the $3x$ to each term inside the parentheses:

$$(3x * x) + (3x * 2)$$

This simplifies to:

$$3x^2 + 6x$$

So, the **product of the algebraic expressions** $3x$ and $(x + 2)$ is $3x^2 + 6x$. Notice how we used exponent rules ($x * x = x^2$) in finding the product.

Multiplying two binomials is another common scenario. For instance, finding the product of $(x + 1)$ and $(x + 3)$ often involves the FOIL method (First, Outer, Inner, Last) or simply distributing:

$$(x + 1)(x + 3)$$

$$= x(x + 3) + 1(x + 3)$$

$$= (x * x) + (x * 3) + (1 * x) + (1 * 3)$$

$$= x^2 + 3x + x + 3$$

$$= x^2 + 4x + 3$$

In this case, $x^2 + 4x + 3$ is the product of the two binomials. This demonstrates how the concept of **product in algebra** involves expanding and simplifying expressions.

The Product in Different Mathematical Contexts

The term "product" isn't confined to basic arithmetic or algebra. It appears in various branches of mathematics, often with a slightly more specialized meaning, but always rooted in the idea of multiplication.

The Cartesian Product in Set Theory

In set theory, the **Cartesian product** is a fundamental operation. It's not about multiplying numbers, but about combining elements from different sets to form new ordered pairs (or tuples).

If you have two sets, $A = \{1, 2\}$ and $B = \{a, b\}$, the Cartesian product of A and B, denoted as $A \times B$, is the set of all possible ordered pairs where the first element comes from A and the second element comes from B.

$$A \times B = \{(1, a), (1, b), (2, a), (2, b)\}$$

Here, $A \times B$ is the "product" of sets A and B. Each element in the resulting set is an ordered pair, formed by taking one element from each of the original sets. This is a key concept in understanding relationships and combinations between sets.

Dot Product and Cross Product in Vector Algebra

In vector algebra, we have two types of "products" for vectors: the dot product and the cross product.

The Dot Product (Scalar Product)

The **dot product** of two vectors results in a single scalar (a number). It's calculated by multiplying corresponding components of the vectors and then summing those products.

If vector $u = [u_1, u_2]$ and vector $v = [v_1, v_2]$, their dot product is:

$$u \cdot v = u_1 \cdot v_1 + u_2 \cdot v_2$$

The dot product has significant applications in physics and geometry, such as calculating work done or determining the angle between vectors. It's a way to "multiply" vectors to get a scalar value representing their relationship.

The Cross Product (Vector Product)

The **cross product**, on the other hand, is defined only for three-dimensional vectors and results in another vector. It's a more complex operation that yields a vector perpendicular to both of the original vectors, with a magnitude related to the area of the parallelogram they form.

The cross product is denoted by ' $\times$ '. The resulting vector's direction is determined by the right-hand rule. It's crucial in fields like physics for calculating torque or magnetic force.

While both are called "products," they have distinct definitions and yield different types of results.

The Product in Calculus: Derivatives and Integrals

Calculus, the study of change, also utilizes the concept of products, particularly in the context of derivatives and integrals.

The Product Rule for Differentiation

When you need to find the derivative of a function that is itself a product of two other functions, you use the **product rule**. This rule is a cornerstone of differential calculus.

If you have a function $f(x) = u(x) * v(x)$, then its derivative, $f'(x)$, is given by:

$$f'(x) = u'(x)v(x) + u(x)v'(x)$$

This means the derivative of a product is the derivative of the first function times the second function, plus the first function times the derivative of the second function. It's a systematic way to find the rate of change of a product of functions.

Integration of Products

Similarly, when integrating products of functions, we often employ a technique called **integration by parts**, which is closely related to the product rule for differentiation. It allows us to transform a complex integral into a simpler one by breaking down the product.

The formula for integration by parts is derived from the product rule:

$$\int u \, dv = uv - \int v \, du$$

This allows us to "undo" differentiation for products, making integration of certain complex functions manageable.

Key Takeaways: What to Remember About Mathematical Products

So, to summarize, when we talk about a **product in math terms**, we're generally referring to:

1. The **result of multiplication**: This is the most common and fundamental definition.
2. The outcome of multiplying two or more **factors** or quantities.
3. A concept that extends from simple numbers to variables, algebraic expressions, sets, vectors, and functions.
4. A key operation with specific rules and applications in various branches of mathematics, including algebra, set theory, vector calculus, and differential calculus.

Understanding the definition of a product is not just about memorizing a term; it's about grasping a foundational mathematical operation that underpins countless calculations and theorems. Whether you're solving a basic multiplication problem or tackling advanced calculus, the concept of a product will be your constant companion. Keep practicing, and the meaning of "product" will become as natural as a simple sum!

In mathematics, the concept of a "product" extends beyond its common usage in arithmetic and becomes a foundational operation rooted in the structure of sets and algebraic systems. At its core, the product of two or more mathematical entities represents the result of combining them through a defined operation that preserves essential properties such as closure, associativity, and commutativity under certain conditions.

Understanding Product in Algebraic Contexts

In algebra, the product is most frequently associated with multiplication, especially when dealing with real or complex numbers. For two numbers a and b , their product $a \times b$ or simply ab is defined as the repeated addition of a , b times, though this intuitive interpretation evolves into a

more abstract notion in advanced mathematics. In vector spaces, the dot product—also known as the scalar product—generalizes multiplication by measuring the projection of one vector onto another, yielding a scalar that encapsulates both magnitude and directional alignment. This operation exemplifies how the product functions not merely as a numerical outcome, but as a meaningful geometric and algebraic interaction. Beyond scalar multiplication, the concept of product manifests in deeper structures such as matrix multiplication, where the product of two matrices results in a new matrix encoding linear transformations. Here, the product is defined through a summation over indices, reflecting a systematic combination of entries that captures change of basis, rotation, scaling, and other transformations. This generalized product underscores the power of the concept to unify diverse mathematical operations under a single, coherent framework.

Key Insights and Structural Properties

The defining feature of a product in mathematics is its dual nature: it is both an operation and a relation that respects the algebraic structure of the underlying set. In group theory, the product corresponds to the binary operation that satisfies closure, associativity, and often the existence of an identity element and inverses. In the context of ring and field theory, products are integrated into a broader arithmetic system where addition and multiplication interact harmoniously, enabling solutions to equations and the construction of number systems. An essential insight is that products preserve symmetry and order in structured ways. For instance, the commutative property of multiplication—where $(ab = ba)$ —reflects a balanced interaction between factors, while non-commutative products, such as matrix multiplication, reveal richer, direction-dependent behaviors. These distinctions are vital in areas ranging from quantum mechanics to cryptography, where the nature of the product directly influences system behavior and computational complexity.

Applications Across Mathematical Disciplines

The utility of mathematical products spans virtually every branch of the discipline. In linear algebra, products define transformations critical to computer graphics, machine learning, and data compression. In calculus, integration and differentiation rely on product rules that govern how quantities change and accumulate. In number theory, multiplicative functions and modular arithmetic products underpin cryptographic algorithms that secure digital communication. Moreover, in functional analysis, infinite products—such as product spaces and infinite series—extend the concept to continuous domains, enabling the modeling of stochastic processes, signal processing, and quantum probability. The flexibility of the product operation allows mathematicians to abstract patterns and build models that describe everything from fluid dynamics to economic markets.

Benefits and Practical Implications

The precise definition and consistent behavior of products offer profound benefits. They provide a language for expressing complex relationships in a compact, computable form. This abstraction enables generalization: a single definition applies across different domains, from discrete integers to continuous real numbers and beyond. As a result, mathematical models become more portable, reusable, and scalable. Furthermore, products empower algorithmic efficiency. Efficient computation of products—whether via naive multiplication or optimized fast Fourier transforms—drives advancements in high-performance computing, data science, and artificial intelligence. In cryptography, carefully constructed products form the backbone of secure key exchange and encryption protocols, illustrating how foundational concepts translate into real-world protection.

Future Outlook and Emerging Frontiers

Looking forward, the role of product in mathematics continues to evolve alongside emerging fields. In quantum computing, tensor products extend classical multiplication to represent entangled states and multi-qubit systems, enabling computational power beyond classical limits. In category theory, products generalize across abstract structures, unifying operations across domains like topology, logic, and computer science. As data grows in complexity and scale, new product-inspired constructs—such as tensor products in deep learning, spectral products in network analysis, and probabilistic products in Bayesian inference—will shape innovation. The mathematical product remains not just a static definition, but a dynamic, expanding paradigm that continues to unlock deeper understanding and transformative applications across science and technology.

The Product in Mathematics: More Than Just Multiplication

In the realm of mathematics, the term "product" carries a specific and fundamental meaning, extending far beyond the everyday understanding of simply multiplying two numbers. While the intuitive notion of a product being the result of multiplication is certainly correct, a deeper dive reveals its pervasive influence across various mathematical disciplines, from basic arithmetic to advanced calculus and abstract algebra. Understanding the definition of a product in mathematical terms is crucial for grasping complex mathematical concepts and solving a wide array of problems.

Defining the Product: The Core Concept

At its most basic, the **product** in mathematics refers to the result obtained when one or more numbers are multiplied together. This operation is fundamental and forms the bedrock of arithmetic. When we say "the product of 3 and 4 is 12," we are stating that 3 multiplied by 4 equals 12. The numbers being multiplied are called **factors**, and the outcome is the product.

This concept can be generalized to include more than two factors. For instance, the product of 2, 3, and 5 is $2 * 3 * 5 = 30$. The order of multiplication does not affect the product due to the associative and commutative properties of multiplication. This is a critical aspect of the definition: the product is a unique value derived from combining these factors.

The Symbolism of Product

The most common symbol used to denote multiplication and thus the calculation of a product is the asterisk (*), the cross (×), or a dot (·). In algebraic expressions, the multiplication symbol is often omitted when variables are involved, with adjacency implying multiplication. For example, 'ab' signifies the product of 'a' and 'b'.

For products involving a sequence of numbers or variables, especially in summation and series notation, the Greek capital letter Pi (Π) is employed. This is known as **product notation** or **Pi notation**. For example, the product of the first 'n' positive integers is represented as:

$$\prod_{i=1}^n i = 1 \times 2 \times 3 \times \dots \times n$$

This notation is incredibly powerful for compactly expressing long chains of multiplications, a common occurrence in areas like combinatorics and probability.

Beyond Simple Multiplication: Products in Different Mathematical Contexts

The definition of a product takes on richer meanings and applications as we move into more advanced mathematical fields. The underlying principle of combining elements to produce a new element remains, but the nature of the elements and the operation of combination can vary significantly.

1. Product of Real Numbers and Integers

As established, the product of two real numbers, 'a' and 'b', is denoted by ' $a \times b$ ' or ' ab ', and results in a unique real number. This is the most basic and universally understood definition. For integers, this product also results in an integer. This elementary definition is the foundation upon which all other mathematical concepts involving products are built. Understanding the properties of multiplication, such as commutativity ($a \times b = b \times a$) and associativity ($a \times (b \times c) = (a \times b) \times c$), is essential when working with products of numbers.

2. Product of Polynomials

In algebra, the product of two polynomials involves distributing each term of one polynomial to every term of the other and then combining like terms. For example, the product of $(x+2)$ and $(x+3)$ is:

$$(x+2)(x+3) = x(x+3) + 2(x+3) = x^2 + 3x + 2x + 6 = x^2 + 5x + 6$$

Here, the resulting polynomial $x^2 + 5x + 6$ is the product of the two binomials. The concept of degree of a polynomial also plays a role; the degree of the product of two polynomials is the sum of their degrees.

3. Cartesian Product of Sets

In set theory, the **Cartesian product**, denoted by a superscript ' $\times$ ', is a different kind of product. It is a set of all possible ordered pairs where the first element comes from one set and the second element comes from another set. For two sets A and B, the Cartesian product $A \times B$ is defined as:

$$A \times B = \{ (a, b) \mid a \in A \text{ and } b \in B \}$$

For instance, if set $A = \{1, 2\}$ and set $B = \{a, b\}$, then the Cartesian product $A \times B$ is $\{(1, a), (1, b), (2, a), (2, b)\}$. This concept is fundamental in understanding relations and functions, and it extends to the product of multiple sets, yielding ordered tuples of elements.

4. Dot Product (Scalar Product) of Vectors

In linear algebra and physics, the **dot product**, also known as the **scalar product**, of two vectors results in a scalar (a single number). It is calculated by multiplying corresponding components of the vectors and summing the results. For two vectors $\mathbf{u} = \langle u_1, u_2, \dots, u_n \rangle$ and $\mathbf{v} = \langle v_1, v_2, \dots, v_n \rangle$, their dot product is:

$$\mathbf{u} \cdot \mathbf{v} = u_1 v_1 + u_2 v_2 + \dots + u_n v_n$$

The dot product has significant geometric interpretations, such as determining the angle between vectors and calculating projections. A dot product of zero indicates that the vectors are orthogonal (perpendicular).

5. Cross Product (Vector Product) of Vectors

Another type of product involving vectors is the **cross product**, or **vector product**, typically defined for vectors in three-dimensional space. Unlike the dot product, the cross product results in another vector. It is calculated using a determinant formula or component-wise operations.

The cross product $\mathbf{u} \times \mathbf{v}$ results in a vector that is perpendicular to both $\mathbf{u}$ and $\mathbf{v}$. Its magnitude is related to the area of the parallelogram formed by the two vectors, and its direction is determined by the right-hand rule. The cross product is crucial in physics for concepts like torque and angular momentum.

6. Product of Matrices

In matrix algebra, the **matrix product** is a complex operation that combines two matrices to produce a third matrix. For two matrices A (of size $m \times n$) and B (of size $n \times p$), their product AB is a matrix of size $m \times p$. The element in the i -th row and j -th column of the product matrix is found by taking the dot product of the i -th row of A and the j -th column of B .

Matrix multiplication is not commutative, meaning $AB \neq BA$ in general. This property has profound implications in areas like linear transformations and solving systems of linear equations.

7. Product Integrals

In calculus, the concept of a product can be extended to integrals. A **product integral** is a generalization of the ordinary Riemann integral. One common form involves the product of function values along a curve, analogous to how a Riemann integral sums function values. Product integrals are used in areas like differential geometry and stochastic calculus, often appearing in the context of solving differential equations and analyzing dynamic systems.

8. Direct Product in Group Theory

In abstract algebra, particularly group theory, the **direct product** is a way to construct a new group from two or more existing groups. The elements of the direct product group are tuples of elements from the constituent groups, and the group operation is performed component-wise. This construction is fundamental for understanding the structure of more complex groups by decomposing them into simpler ones.

The Importance of the Product in Mathematical Reasoning

The consistent thread across all these definitions is the idea of combining components to create a new entity. The product is not merely an arithmetic operation; it's a fundamental mathematical construct that:

- Quantifies relationships:** The product of two numbers gives a new quantity that reflects their combined magnitude. The dot product of vectors quantifies their alignment.
- Builds complexity:** Products allow us to construct more complex mathematical objects from simpler ones. The Cartesian product builds pairs from elements, and matrix multiplication combines linear transformations.
- Enables generalization:** The abstract notion of a product, often represented by Π , allows mathematicians to express and work with products of arbitrary length or complexity.
- Forms the basis for advanced theories:** Concepts like determinants, eigenvalues, and invariants

in linear algebra, or norms and inner products in functional analysis, rely heavily on various forms of products.

Conclusion: A Universal Mathematical Operation

In conclusion, the definition of a product in mathematics is multifaceted, evolving from the simple act of multiplication to sophisticated operations in abstract algebra and calculus. Whether it's the result of multiplying numbers, the combination of elements from sets, the scalar result of vector operations, or the complex outcome of matrix multiplication, the product signifies a fundamental way of combining mathematical entities. Its ubiquity across different branches of mathematics underscores its importance as a core concept, essential for building, analyzing, and understanding the intricate world of mathematical structures and their applications.

Questions & Answers About definition of product in math terms

No	Question	Answer
1	What's the simplest way to define 'product' in math?	In its most basic form, the product in mathematics is the result you get when you multiply two or more numbers together.
2	Is 'product' just about multiplication, or is there more to it?	While multiplication is the core, the concept of a product extends to more complex scenarios like the Cartesian product of sets or the product of functions, which involve combining elements from different mathematical structures.
3	When we talk about the 'product' of numbers, what are those numbers called?	The numbers being multiplied to get a product are called factors or multiplicands.
4	Can you give an example of a simple product in action?	Sure! If you multiply 5 by 3, the product is 15 ($5 \times 3 = 15$).

5	Does the order of numbers matter when calculating a product?	For regular multiplication of numbers, no. The commutative property states that the order of factors doesn't change the product (e.g., $5 \times 3 = 3 \times 5 = 15$).
6	What's a 'Cartesian product' in mathematics?	A Cartesian product is a way to combine elements from two or more sets. For example, the Cartesian product of set $A = \{1, 2\}$ and set $B = \{a, b\}$ is $\{(1, a), (1, b), (2, a), (2, b)\}$.
7	How is the 'product' used in algebra?	In algebra, 'product' refers to the result of multiplying algebraic expressions, such as polynomials. For instance, the product of $(x+1)$ and $(x+2)$ is $x^2 + 3x + 2$.
8	What about the 'product' of functions?	The product of two functions, $f(x)$ and $g(x)$, is a new function, often written as $(f*g)(x)$, where $(f*g)(x) = f(x) * g(x)$.
9	In calculus, what does 'product rule' refer to?	The product rule is a formula used to find the derivative of a product of two functions. It's a fundamental tool for differentiation.
10	Is the term 'product' ever used for division or subtraction?	No, 'product' is exclusively associated with multiplication. Division results in a quotient, and subtraction results in a difference.
