

How To Find The Equation Of A Parabola

Determining the Equation of a Parabola: A Comprehensive Guide

Parabolas, with their characteristic U-shaped curves, appear frequently in various scientific and engineering applications. Understanding how to derive their equations is crucial for modeling diverse phenomena, from projectile trajectories to antenna designs. This comprehensive guide provides a step-by-step approach to finding the equation of a parabola, covering various scenarios and highlighting important considerations.

A parabola is a set of all points in a plane that are equidistant from a fixed line (the directrix) and a fixed point (the focus) not on the line. This fundamental definition allows us to derive the standard equations for different orientations and positions of

the parabola. This will explore methods for finding the equation of a parabola given various initial conditions, including points, vertices, foci, and directrices.

Standard Forms of Parabola Equations

Before delving into the methods, let's review the standard forms of parabola equations: **Vertical Axis of Symmetry:** • **Vertex at (h, k) :** $(x - h)^2 = 4p(y - k)$ • p is the distance from the vertex to the focus (positive for upward opening, negative for downward opening). **Horizontal Axis of Symmetry:** • **Vertex at (h, k) :** $(y - k)^2 = 4p(x - h)$ • p is the distance from the vertex to the focus (positive for rightward opening, negative for leftward opening). **Understanding 'p':** The value of 'p' dictates the parabola's width. A larger magnitude of 'p' corresponds to a narrower parabola, while a smaller magnitude results in a wider parabola.

Finding the Equation of a Parabola Given the Vertex and a Point

1. **Identify the Vertex:** Determine the coordinates (h, k) of the vertex. 2. **Identify a Point:** Note the coordinates (x, y) of a point on the parabola. 3. **Determine 'p' and the Orientation:** Based on the position of the point relative to the vertex, determine whether the parabola opens upward, downward, rightward, or leftward. 4. **Substitute:** Substitute the vertex coordinates (h, k)

and the coordinates of the point (x, y) into the appropriate standard form equation. 5. *Solve for 'p'*: Solve the resulting equation for the parameter 'p'. **Example:** Find the equation of a parabola with vertex (2, 1) and passing through the point (4, 3). $(x - 2)^2 = 4p(y - 1)$ Substitute (4, 3): $(4 - 2)^2 = 4p(3 - 1) \Rightarrow 4 = 8p \Rightarrow p = 1/2$ Therefore, the equation is $(x - 2)^2 = 2(y - 1)$.

Finding the Equation Given the Focus and Directrix

1. Determine the Vertex: The vertex is halfway between the focus and the directrix. 2. **Identify the Axis of Symmetry**: The axis of symmetry is the line perpendicular to the directrix and passing through the focus and the vertex. 3. Determine 'p': 'p' is the distance between the vertex and the focus (or between the vertex and the directrix). 4. *Determine the Orientation*: The direction of opening depends on the relative positions of the focus and directrix. 5. **Substitute**: Use the appropriate standard form equation (vertical or horizontal). Substitute the vertex coordinates (h, k) and the value of 'p' to complete the equation.

Example: A parabola has focus (0, 3) and directrix $y = -1$. Vertex: (0, 1) $p = 4$ Equation: $(x - 0)^2 = 4(4)(y - 1) \Rightarrow x^2 = 16(y - 1)$.

Finding the Equation Given Three Points

If three points are given, we can use a system of equations: 1. *Choose appropriate form*: Choose the standard form corresponding to the suspected axis of symmetry (vertical or

horizontal). 2. *Substitute Points*: Substitute the coordinates of each point into the chosen form equation. This yields three equations with three unknowns (a, h, and k). 3. **Solve the System**: Solve the resulting system of equations to find the values of a, h, and k, which determine the equation of the parabola.

Benefits of Knowing the Equation of a Parabola

- Modeling real-world phenomena: Parabolas accurately represent trajectories of projectiles, cable shapes in suspension bridges, and cross-sections of reflectors in telescopes and car headlights.
- *Optimization problems*: Finding the maximum or minimum value of a quadratic function is often used in optimization problems in fields like engineering and economics.
- Analysis of geometric shapes: The equation allows a complete understanding of the shape's properties, including its orientation, width, and position.
- **Solving equations**: If a parabola is graphed as $y = a(x - h)^2 + k$, where a, h, and k are constants, we can use the equation to find the roots (x-intercepts) and the vertex.

Advanced Topics

Parabolas with Axes Oblique to the Coordinate Axes

In cases where the axis of symmetry is not parallel to the x- or y-axis, more complex methods are needed, often involving rotation

Parabolas are more than just pretty curves that appear in math textbooks; they're fundamental shapes that describe the trajectories of projectiles, the design of satellite dishes, and even the arches of bridges. Understanding how to find the equation of a parabola is a key skill in algebra and geometry, opening doors to analyzing and predicting these fascinating phenomena. If you've ever stared at a graph and wondered, "What's the formula behind that U-shape?", you're in the right place. We're going to demystify the process of finding the equation of a parabola, breaking it down into manageable steps. Whether you're given two points and the vertex, or just a general understanding of its orientation, there are several powerful methods at your disposal. We'll explore each one, ensuring you walk away feeling confident and capable of tackling any parabola problem. So, let's dive in and uncover the secrets behind these ubiquitous curves!

Understanding the Anatomy of a Parabola

Before we start plugging in numbers, it's crucial to understand the basic building blocks of a parabola. Think of it as learning the language before you can write a novel. * **Vertex:** This is the "turning point" of the parabola. It's either the lowest point (if the parabola opens upwards) or the highest point (if it opens downwards). The vertex is a crucial piece of information for

determining the parabola's equation. * **Axis of Symmetry:** *

This is an imaginary line that cuts the parabola directly in half, creating a mirror image on both sides. For parabolas that open up or down, this is a vertical line passing through the vertex. For parabolas that open left or right, it's a horizontal line. *

Focus: This is a special point located inside the parabola.

Every point on the parabola is equidistant from the focus and the directrix. * **Directrix:** This is a line located outside the

parabola. As mentioned, the distance from any point on the parabola to the focus is equal to the distance from that point to the directrix. * **Opening Direction:** Parabolas can open upwards, downwards, to the left, or to the right. This direction significantly impacts the form of the equation.

The Standard Forms of a Parabola's Equation

The way a parabola's equation is written depends on its orientation. There are two primary standard forms to remember:

1. The Upward or Downward Opening Parabola (Vertical Axis of Symmetry)

When a parabola opens either upwards or downwards, its axis of symmetry is a vertical line. The standard form of its equation is:

$$(x - h)^2 = 4p(y - k)$$

* **(h, k)** represents the coordinates of the **vertex**. This is your most important starting point. * **p** is a constant that

determines how wide or narrow the parabola is and the distance from the vertex to the focus (and from the vertex to the directrix). * If $p > 0$, the parabola opens **upwards**. * If $p < 0$, the parabola opens **downwards**. Another common, and often more user-friendly, form for upward/downward parabolas is:

$$y = ax^2 + bx + c$$

While this form doesn't explicitly show the vertex (h, k) or 'p', you can find the vertex using the formula $h = -b / 2a$, and then substitute 'h' back into the equation to find 'k'. The coefficient 'a' relates to 'p' as $a = 1 / (4p)$.

2. The Leftward or Rightward Opening Parabola (Horizontal Axis of Symmetry)

For parabolas that open horizontally (to the left or right), the standard form is slightly different:

$$(y - k)^2 = 4p(x - h)$$

* (h, k) again represents the coordinates of the **vertex**. * p is the same constant, affecting the parabola's width and distance to the focus/directrix. * If $p > 0$, the parabola opens to the **right**. * If $p < 0$, the parabola opens to the **left**. Similar to the vertical case, a more general form is:

$$x = ay^2 + by + c$$

Here, the vertex's x-coordinate can be found using $k = -b / 2a$, and then substituting 'k' to find 'h'. The relationship

between 'a' and 'p' is $a = 1 / (4p)$.

Methods to Find the Equation of a Parabola

Now that we're familiar with the forms, let's explore the common scenarios and how to solve them.

Method 1: Given the Vertex and a Point

This is perhaps the most straightforward scenario. If you know the vertex (h, k) and one other point (x, y) that lies on the parabola, you can determine its equation. **Scenario A:**

Parabola Opens Up or Down 1. **Start with the vertex form:** $y = a(x - h)^2 + k$ 2. **Substitute the vertex coordinates:** Plug in the values for 'h' and 'k' into the equation. 3. **Use the extra point:** Substitute the x and y coordinates of the given point into the equation. 4. **Solve for 'a':** This is the only unknown left, so you can solve for it. 5. **Write the final equation:** Substitute the value of 'a' back into the vertex form. *Example: Find the equation of a parabola with vertex (2, 3) that passes through the point (4, 7).* 1. Vertex form: $y = a(x - h)^2 + k$ 2. Substitute vertex (2, 3): $y = a(x - 2)^2 + 3$ 3. Substitute point (4, 7): $7 = a(4 - 2)^2 + 3$ 4. Solve for 'a': $7 = a(2)^2 + 3$ $7 = 4a + 3$ $4 = 4a$ $a = 1$ 5. Final equation: $y = 1(x - 2)^2 + 3$ or $y = (x - 2)^2 + 3$ **Scenario B:**

Parabola Opens Left or Right 1. **Start with the vertex form:** $x = a(y - k)^2 + h$ 2. **Substitute the vertex coordinates:** Plug in the values for 'h' and 'k'. 3. **Use the extra point:** Substitute the x and y coordinates of the given point. 4. **Solve for 'a':** Find the value of 'a'. 5. **Write the final equation:**

Substitute 'a' back into the vertex form. *Example: Find the equation of a parabola with vertex (-1, 5) that passes through the point (3, 1).* 1. Vertex form: $x = a(y - k)^2 + h$ 2. Substitute vertex (-1, 5): $x = a(y - 5)^2 + (-1) \Rightarrow x = a(y - 5)^2 - 1$ 3. Substitute point (3, 1): $3 = a(1 - 5)^2 - 1$ 4. Solve for 'a': $3 = a(-4)^2 - 1$ $3 = 16a - 1$ $4 = 16a$ $a = 4/16 = 1/4$ 5. Final equation: $x = (1/4)(y - 5)^2 - 1$

Method 2: Given Three Points

This method is a bit more involved but can be solved systematically. You'll typically use the general form of the parabola's equation. **Scenario A: Parabola Opens Up or Down ($y = ax^2 + bx + c$)** 1. ****Set up a system of equations:**** For each of the three given points (x_1, y_1) , (x_2, y_2) , and (x_3, y_3) , substitute their coordinates into the equation $y = ax^2 + bx + c$. This will give you three separate equations with three unknowns (a, b, and c). $* y_1 = ax_1^2 + bx_1 + c$ $* y_2 = ax_2^2 + bx_2 + c$ $* y_3 = ax_3^2 + bx_3 + c$ 2. ****Solve the system of equations:**** You can use methods like substitution, elimination, or matrix operations to solve for a, b, and c. 3. ****Write the final equation:**** Substitute the values of a, b, and c back into $y = ax^2 + bx + c$. *Example: Find the equation of a parabola that passes through the points (1, 4), (2, 9), and (3, 16).* 1. Set up equations: $* 4 = a(1)^2 + b(1) + c \Rightarrow 4 = a + b + c$ (Eq 1) $* 9 = a(2)^2 + b(2) + c \Rightarrow 9 = 4a + 2b + c$ (Eq 2) $* 16 = a(3)^2 + b(3) + c \Rightarrow 16 = 9a + 3b + c$ (Eq 3) 2. Solve the system: $* \text{Subtract Eq 1 from Eq 2: } (9 - 4) = (4a - a) + (2b - b) + (c - c) \Rightarrow 5 = 3a + b$ (Eq 4) $* \text{Subtract Eq 2 from Eq 3: } (16 - 9) = (9a - 4a) + (3b - 2b) + (c - c) \Rightarrow 7 = 5a + b$ (Eq 5) *

Subtract Eq 4 from Eq 5: $(7 - 5) = (5a - 3a) + (b - b) \Rightarrow 2 = 2a$
 $\Rightarrow a = 1$ * Substitute $a = 1$ into Eq 4: $5 = 3(1) + b \Rightarrow 5 = 3 + b$
 $\Rightarrow b = 2$ * Substitute $a = 1$ and $b = 2$ into Eq 1: $4 = 1 + 2 + c$
 $\Rightarrow 4 = 3 + c \Rightarrow c = 1$ 3. Final equation: $y = 1x^2 + 2x + 1$ or $y = x^2 + 2x + 1$ **Scenario B: Parabola Opens Left or Right ($x = ay^2 + by + c$)** The process is identical to Scenario A, but you'll substitute the x and y coordinates into the equation $x = ay^2 + by + c$, and solve for a, b, and c.

Method 3: Given the Vertex, Focus, and Directrix (and understanding 'p')

If you're given the vertex (h, k) and either the focus or the directrix, you can find the value of 'p' and thus the equation. *

****Distance to Focus/Directrix:**** The distance between the vertex and the focus is 'p', and the distance between the vertex and the directrix is also 'p'. The sign of 'p' depends on the direction of opening. ****Scenario A: Parabola Opens Up or Down**** 1.

****Identify the vertex (h, k) .** 2. ****Determine 'p':**** * If the focus is above the vertex, the parabola opens upwards, and p is positive. The focus will be at $(h, k + p)$. * If the focus is below the vertex, the parabola opens downwards, and p is negative. The focus will be at $(h, k - p)$. * If the directrix is above the vertex ($y = k + p$), the parabola opens downwards, and p is negative. * If the directrix is below the vertex ($y = k - p$), the parabola opens upwards, and p is positive. 3. ****Use the standard form:**** $(x - h)^2 = 4p(y - k)$ *Example: Find the equation of a parabola with vertex $(1, -2)$ and focus $(1, -4)$.* 1. Vertex $(h, k) = (1, -2)$. 2. The focus is $(1, -4)$. Since the x-coordinate is the same and the y-coordinate

is lower, the parabola opens downwards. The distance from vertex (1, -2) to focus (1, -4) is 2 units. So, $p = -2$ (negative because it opens down). 3. Standard form: $(x - h)^2 = 4p(y - k)$ $(x - 1)^2 = 4(-2)(y - (-2))$ $(x - 1)^2 = -8(y + 2)$ ****Scenario B: Parabola Opens Left or Right**** 1. ****Identify the vertex (h, k).**** 2. ****Determine 'p':**** * If the focus is to the right of the vertex, the parabola opens to the right, and p is positive. The focus will be at $(h + p, k)$. * If the focus is to the left of the vertex, the parabola opens to the left, and p is negative. The focus will be at $(h - p, k)$. * If the directrix is to the right of the vertex ($x = h + p$), the parabola opens to the left, and p is negative. * If the directrix is to the left of the vertex ($x = h - p$), the parabola opens to the right, and p is positive. 3. ****Use the standard form:**** $(y - k)^2 = 4p(x - h)$ *Example: Find the equation of a parabola with vertex (-3, 0) and directrix $x = -5$.* 1. Vertex $(h, k) = (-3, 0)$. 2. The directrix is $x = -5$. This is a vertical line to the left of the vertex. This means the parabola opens to the right. The distance from the vertex $(-3, 0)$ to the directrix $x = -5$ is 2 units. So, $p = 2$ (positive because it opens right). 3. Standard form: $(y - k)^2 = 4p(x - h)$ $(y - 0)^2 = 4(2)(x - (-3))$ $y^2 = 8(x + 3)$

Key Takeaways and Tips for Success

****Sketch it out:**** Whenever possible, sketch the parabola based on the given information. This can help you visualize the opening direction and the relationship between the vertex, focus, and directrix. ****Identify the vertex:**** The vertex is almost always your starting point. Make sure you can identify it correctly. ****Recognize the orientation:**** Is the parabola

opening vertically (up/down) or horizontally (left/right)? This dictates which standard form to use. * **Don't forget the 'p':** The value of 'p' is crucial for defining the parabola's width and its relationship to the focus and directrix. Pay close attention to its sign. * **Practice makes perfect:** The more you practice solving different types of parabola problems, the more comfortable and confident you'll become.

Understanding Parabolas: A Comprehensive Guide to Finding Their Equations A parabola is one of the most elegant and widely studied curves in mathematics, representing a specific type of quadratic relationship between variables. Defined as the set of all points equidistant from a fixed point—the focus—and a fixed line—the directrix—parabolas appear in nature, physics,

engineering, and the arts. Grasping how to determine their equation is essential for students, educators, and professionals working with quadratic functions, as it forms the foundation for analyzing real-world phenomena involving curved trajectories, focus properties, and optimization. To find the equation of a parabola, it begins with understanding its standard forms, which reflect the parabola's orientation and position in the coordinate plane. The most common forms are the vertical and horizontal versions: for a parabola that opens upward or downward, the equation takes the form $y = ax^2 + bx + c$; when it opens left or right, it becomes $x = ay^2 + by + c$. These forms directly reveal key characteristics such as the vertex, axis of symmetry, and direction of opening, all of which are critical in constructing the equation properly. The vertex form, expressed as $y = a(x - h)^2 + k$, offers a powerful shortcut when the vertex (h, k) is known. Here, a determines the parabola's width and direction—positive values indicate upward opening, negative values downward—while the vertex serves as the curve's turning point. This form simplifies both graphing and deriving the equation from geometric descriptions, making it particularly useful in applied contexts such as projectile motion or satellite dish design. Beyond the standard forms, identifying a parabola's equation may require interpreting real-world data or word problems. In such cases, recognizing the defining geometric properties—such as the focus, directrix, or axis—is essential. For example, if a scenario describes a parabola with vertex at the origin and passing through a specific point, substituting those coordinates into the general equation allows

solving for the unknown coefficient. Similarly, using the definition involving the focus and directrix, one can derive the equation by applying the distance formula and eliminating square roots through algebraic manipulation. Mastering the process of finding a parabola's equation unlocks deeper insights into quadratic behavior. It enables accurate modeling of phenomena like the flight path of a thrown ball, the shape of reflective surfaces in optics, and the optimization of parabolic structures in architecture. The ability to translate geometric intuition into algebraic expressions strengthens analytical skills and supports advanced study in calculus, engineering, and data science.

Looking ahead, as technology continues to evolve, tools like dynamic graphing software and AI-assisted equation solvers are enhancing how parabolas are taught and discovered. Yet, the core principles—understanding form, recognizing key features, and applying geometric definitions—remain irreplaceable. Whether through manual derivation or digital exploration, finding the equation of a parabola remains a vital skill, bridging theory and application in both academic and real-world settings.

Understanding parabolas and their equations is not merely an academic exercise; it is a gateway to interpreting and shaping the curved world around us. With clarity and precision, one can uncover the mathematical essence of parabolic motion, unlocking new possibilities in learning, innovation, and problem-solving across disciplines.

What is a Parabola? The Geometric Definition and Its Equation

At its core, a parabola is defined as the set of all points in a plane that are equidistant from a fixed point (the focus) and a fixed line (the directrix). This elegant geometric definition directly leads to its algebraic representation. The standard forms of a parabola's equation depend on its orientation. For parabolas opening upwards or downwards, the equation typically takes the form:

$$(x - h)^2 = 4p(y - k)$$

where: * (h, k) represents the coordinates of the **vertex** of the parabola. * 'p' is the directed distance from the vertex to the **focus**. If $p > 0$, the parabola opens upwards; if $p < 0$, it opens downwards. For parabolas opening to the right or left, the equation is:

$$(y - k)^2 = 4p(x - h)$$

where: * (h, k) again denotes the **vertex**. * 'p' is the directed distance from the vertex to the **focus**. If $p > 0$, the parabola opens to the right; if $p < 0$, it opens to the left. It's also crucial to recognize the **general form of a quadratic equation** that represents a parabola:

$$y = ax^2 + bx + c$$

(for parabolas opening vertically)

$$x = ay^2 + by + c$$

(for parabolas opening horizontally) While these forms might look different, they are fundamentally related. The coefficient 'a' in these general forms dictates the parabola's width and direction of opening. A positive 'a' means opening upwards (or to the right), and a negative 'a' means opening downwards (or to the left). The larger the absolute value of 'a', the narrower the parabola.

Methods for Finding the Equation of a Parabola

There isn't a single "one-size-fits-all" method for finding the equation of a parabola. The approach you take will depend on the information provided. We'll explore the most common scenarios:

1. Using the Vertex and a Point on the Parabola

This is one of the most straightforward methods. If you know the coordinates of the vertex (h, k) and at least one other point (x, y) that lies on the parabola, you can determine the equation.

Steps:

1. **Identify the form of the equation:** Determine if the parabola opens vertically or horizontally. This can often be inferred from a sketch or a description.
2. **Substitute the vertex coordinates:** Plug the values of h and k into the appropriate standard form:
 - * Vertical: $(x - h)^2 = 4p(y - k)$
 - * Horizontal: $(y - k)^2 = 4p(x - h)$
3. **Substitute the coordinates of the known point:** Plug the values of x and y from the additional point into the equation.
4. **Solve for p :** You'll now have an equation with only p as the unknown. Solve for p .
5. **Write the final equation:** Substitute the values of h , k , and p back into the standard form.

Example: Find the equation of a parabola with vertex at $(2, 3)$ that passes through the point $(4, 7)$.

- * The vertex is $(2, 3)$, so $h = 2$ and $k = 3$.
- * Let's assume it opens vertically. The equation form is $(x - h)^2 = 4p(y - k)$.
- * Substitute the vertex: $(x - 2)^2 = 4p(y - 3)$.
- * Substitute the point $(4, 7)$: $(4 - 2)^2 = 4p(7 - 3)$.
- * Simplify: $(2)^2 = 4p(4)$.
- * $4 = 16p$.
- * Solve for p : $p = \frac{1}{4}$.

$= 4/16 = 1/4$. * Since p is positive, the parabola opens upwards, which is consistent with our assumption. * The final equation is: $(x - 2)^2 = 4(1/4)(y - 3)$, which simplifies to $(x - 2)^2 = y - 3$.

2. Using the General Form ($y = ax^2 + bx + c$) and Points

If you're given the equation in its general form and need to find the specific coefficients (a , b , c), or if you're given three points on the parabola, this method is useful. **Steps:** 1. **Set up a system of equations:** For each point (x, y) given, substitute its coordinates into the general equation $y = ax^2 + bx + c$. This will create a system of linear equations with ' a ', ' b ', and ' c ' as the unknowns. 2. **Solve the system of equations:** Use methods like substitution, elimination, or matrices to solve for the values of ' a ', ' b ', and ' c '. 3. **Write the final equation:** Substitute the solved values of ' a ', ' b ', and ' c ' back into the general form.

Example: Find the equation of the parabola that passes through the points $(1, 5)$, $(-1, 1)$, and $(2, 7)$. * Using $y = ax^2 + bx + c$: * For $(1, 5)$: $5 = a(1)^2 + b(1) + c \Rightarrow a + b + c = 5$ (Equation 1) * For $(-1, 1)$: $1 = a(-1)^2 + b(-1) + c \Rightarrow a - b + c = 1$ (Equation 2) * For $(2, 7)$: $7 = a(2)^2 + b(2) + c \Rightarrow 4a + 2b + c = 7$ (Equation 3)

* **Solving the system:** * Subtract Equation 2 from Equation 1: $(a + b + c) - (a - b + c) = 5 - 1 \Rightarrow 2b = 4 \Rightarrow b = 2$. * Substitute $b = 2$ into Equation 1 and Equation 2: * $a + 2 + c = 5 \Rightarrow a + c = 3$ (Equation 4) * $a - 2 + c = 1 \Rightarrow a + c = 3$ (This confirms our value of b) * Substitute $b = 2$ into Equation 3: $4a + 2(2) + c = 7 \Rightarrow 4a + 4 + c = 7 \Rightarrow 4a + c = 3$ (Equation 5) * Subtract Equation 4 from Equation 5: $(4a + c) - (a + c) = 3 - 3 \Rightarrow 3a = 0 \Rightarrow a = 0$. * Wait! If $a = 0$, it's not a parabola, but a

line. Let's recheck the calculations. *Rethinking the process. It's crucial to ensure the points actually form a parabola.* Let's assume there was a calculation error in the example points or the prompt. For a true parabola, 'a' cannot be zero. Let's use a different set of points for a more illustrative example: (1, 1), (2, 4), (3, 9) which clearly lie on $y = x^2$. * For (1, 1): $a + b + c = 1$ * For (2, 4): $4a + 2b + c = 4$ * For (3, 9): $9a + 3b + c = 9$ * Subtracting the first from the second: $3a + b = 3$ * Subtracting the second from the third: $5a + b = 5$ * Subtracting these new equations: $2a = 2 \Rightarrow a = 1$. * Substitute $a = 1$ into $3a + b = 3 \Rightarrow 3(1) + b = 3 \Rightarrow b = 0$. * Substitute $a = 1$ and $b = 0$ into $a + b + c = 1 \Rightarrow 1 + 0 + c = 1 \Rightarrow c = 0$. * The equation is $y = 1x^2 + 0x + 0$, or $y = x^2$.

3. Using the Focus and Directrix

This method directly applies the geometric definition of a parabola. **Steps:** 1. **Recall the distance formula:** The distance between two points (x_1, y_1) and (x_2, y_2) is $\sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$. 2. **Express distance to focus:** Let the focus be (f_x, f_y) . The distance from any point (x, y) on the parabola to the focus is $\sqrt{(x - f_x)^2 + (y - f_y)^2}$. 3. **Express distance to directrix:** The directrix is a line. The distance from a point (x, y) to a vertical line $x = d$ is $|x - d|$. The distance to a horizontal line $y = d$ is $|y - d|$. 4. **Set distances equal:** According to the definition, the distance to the focus equals the distance to the directrix. 5. **Square both sides:** To eliminate the square root, square both sides of the equation. 6. **Simplify and rearrange:** Expand and rearrange the terms to arrive at the equation of the

parabola. **Example:** Find the equation of a parabola with focus at (0, 2) and directrix $y = -2$. * The focus is (0, 2). * The directrix is $y = -2$. * Let (x, y) be a point on the parabola. * Distance to focus: $\sqrt{(x - 0)^2 + (y - 2)^2} = \sqrt{x^2 + (y - 2)^2}$ * Distance to directrix: $|y - (-2)| = |y + 2|$ * Set distances equal: $\sqrt{x^2 + (y - 2)^2} = |y + 2|$ * Square both sides: $x^2 + (y - 2)^2 = (y + 2)^2$ * Expand: $x^2 + (y^2 - 4y + 4) = (y^2 + 4y + 4)$ * Simplify: $x^2 + y^2 - 4y + 4 = y^2 + 4y + 4$ * Subtract y^2 and 4 from both sides: $x^2 - 4y = 4y$ * Add 4y to both sides: $x^2 = 8y$ * The equation of the parabola is **$x^2 = 8y$** . * We can also write this as $y = (1/8)x^2$, confirming the vertex is at (0,0) and it opens upwards.

4. Using the Vertex Form ($y = a(x - h)^2 + k$)

This form is particularly useful when the vertex is known.

Steps: 1. **Substitute the vertex coordinates:** Plug in 'h' and 'k' into the form $y = a(x - h)^2 + k$. 2. **Use a known point to find 'a':** Substitute the coordinates of another point (x, y) on the parabola into the equation and solve for 'a'. 3. **Write the final equation:** Substitute the determined value of 'a' back into the vertex form. **Example:** Find the equation of a parabola with vertex at (-1, 4) that passes through the point (1, 12). * Vertex is (-1, 4), so $h = -1$ and $k = 4$. * The form is $y = a(x - (-1))^2 + 4 \Rightarrow y = a(x + 1)^2 + 4$. * Substitute the point (1, 12): $12 = a(1 + 1)^2 + 4$. * $12 = a(2)^2 + 4$. * $12 = 4a + 4$. * Subtract 4 from both sides: $8 = 4a$. * Solve for 'a': $a = 2$. * The final equation is **$y = 2(x + 1)^2 + 4$** .

Key Concepts and Terminology for Understanding Parabolas

To truly master finding the equation of a parabola, familiarize yourself with these essential terms:

- Vertex:** The turning point of the parabola, where the curve changes direction. It's either the lowest or highest point (for vertical parabolas) or the leftmost or rightmost point (for horizontal parabolas).
- Axis of Symmetry:** A line that divides the parabola into two mirror images. It passes through the vertex. For vertical parabolas, it's $x = h$; for horizontal parabolas, it's $y = k$.
- Focus:** A fixed point inside the parabola. All points on the parabola are equidistant from the focus and the directrix.
- Directrix:** A fixed line outside the parabola. All points on the parabola are equidistant from the focus and the directrix.
- Focal Length (p):** The directed distance from the vertex to the focus. It also relates to the distance from the vertex to the directrix.
- Latus Rectum:** A line segment passing through the focus, perpendicular to the axis of symmetry, with endpoints on the parabola. Its length is $|4p|$.

Tips for Success When Finding Parabola Equations

- Visualize:** Whenever possible, sketch the parabola based on the given information. This can help you determine the orientation and general shape.
- Identify the given information:** Clearly note what information you have: vertex,

focus, directrix, points on the curve. * **Choose the appropriate form:** Select the standard or vertex form that best suits the given data. * **Double-check your calculations:** Algebraic errors are common. Carefully review each step, especially when solving systems of equations or simplifying expressions. * **Understand the role of 'a' and 'p':** The sign of 'a' (in $y = ax^2 + bx + c$ or $y = a(x-h)^2 + k$) and the sign of 'p' (in the standard form) both indicate the direction of opening. * **Practice, Practice, Practice:** The more problems you solve, the more comfortable and proficient you'll become.

Questions & Answers About how to find the equation of a parabola

No	Question	Answer
1	I know two points a parabola passes through and its vertex. How do I find its equation?	Since you have the vertex (h, k) , use the vertex form of the parabola: $y = a(x - h)^2 + k$. Substitute the coordinates of the vertex. Then, plug in the coordinates of one of the other points to solve for 'a'. The equation is now complete!
2	What's the easiest way to find the equation if I have the vertex and one other point?	The vertex form, $y = a(x - h)^2 + k$, is your best friend here. Plug in the vertex (h, k) . Then, use the other point (x, y) to solve for 'a' by rearranging the equation.
3	I'm given the focus and the directrix of a parabola. How do I write its equation?	The definition of a parabola is the set of all points equidistant from the focus and the directrix. Let (x, y) be a point on the parabola. Use the distance formula to express the distance from (x, y) to the focus and the distance from (x, y) to the directrix. Set these distances equal and simplify to get the equation.
4	How can I find the equation of a parabola if I know its x-intercepts and one other point?	Use the intercept form: $y = a(x - r_1)(x - r_2)$, where r_1 and r_2 are the x-intercepts. Substitute the values of the intercepts. Then, plug in the coordinates of the other point (x, y) to solve for 'a'.

5	What's the standard form equation of a parabola, and how do I use it?	The standard forms are $y = ax^2 + bx + c$ (opens up/down) or $x = ay^2 + by + c$ (opens left/right). If you have the vertex and 'a', you can plug them into $y = a(x - h)^2 + k$ and expand to get this form. Or, if given three points, you can substitute them into the standard form equations to create a system of linear equations to solve for 'a', 'b', and 'c'.
6	I have a quadratic equation like $y = 2x^2 - 8x + 6$. How do I find the vertex and then the vertex form?	To find the x-coordinate of the vertex, use $x = -b / 2a$. Substitute this x-value back into the equation to find the y-coordinate of the vertex (h, k). Then, use the vertex form $y = a(x - h)^2 + k$, plugging in your 'a' value from the original equation and the found vertex coordinates.
7	My parabola opens horizontally. How does that change how I find its equation?	If it opens horizontally, the equation will be in the form $x = a(y - k)^2 + h$, where (h, k) is the vertex. You'll use similar methods as with vertical parabolas, but you'll solve for 'a' using points and the vertex, and the roles of x and y are swapped in terms of the squared term.
8	How do I determine the 'a' value in the vertex form of a parabola?	The 'a' value determines the parabola's width and direction. If you know the vertex and another point, substitute both into $y = a(x - h)^2 + k$. Then, isolate and solve for 'a'. A positive 'a' opens upwards, negative opens downwards, a larger a means a narrower parabola.

9	What if I'm given three points that lie on a parabola, and I don't know the vertex or intercepts?	You can use the standard form $y = ax^2 + bx + c$. Substitute the coordinates of each of the three points into this equation to create a system of three linear equations with three unknowns (a, b, and c). Solve this system (using substitution or elimination) to find the values of a, b, and c.
